We demonstrate amplification of picosecond laser pulses to 40 mJ at a 2 kHz pulse repetition frequency (PRF) from a two-stage cryogenic chirped-pulse Yb:YAG amplifier, composed of a regenerative amplifier (RGA) and a two-pass booster amplifier. The RGA produces 8.2 mJ of energy at 2 kHz PRF and 13.2 mJ at 1 kHz PRF with excellent energy stability ( $\sim 0.3\%$  rms) and beam quality ( $M^2 < 1.1$ ). Pulse stretching and compression are achieved by using a chirped fiber Bragg grating and a multilayer dielectric grating pair, respectively. Compressed 15 ps pulses from the RGA are obtained with a throughput efficiency of  $\sim 80\%$  ( $\sim 6.5$  mJ for 2 kHz). The booster amplifier further amplifies the pulses to 40 mJ at 2 kHz PRF, and  $\sim 32$  mJ,  $\sim 15$  ps pulses are expected after compression. The amplifier chain seeded from a femtosecond Yb-fiber laser enables the optical self-synchronization between signal and pump in optical parametric chirped-pulse amplifier applications. © 2010 Optical Society of America

Ultrabroadband high-power optical parametric chirped-pulse amplification (OPCPA) [1] is considered one of the most promising techniques for a driving source in attosecond science because of several interesting capabilities, such as few-cycle-pulse amplification without the need for external nonlinear spectral broadening followed by compression, wavelength selective coverage from the visible to mid-IR, and direct amplification of passively carrier-envelope-phase stabilized mid-IR pulses generated via difference-frequency generation. The ultrabroadband few-cycle OPCPA technique benefits from ps pump lasers, in comparison with ns lasers, because a low stretching factor results in good compressibility, and high-peak-power pumping enables broadband phase matching in short nonlinear media. However, the availability of suitable ps pump sources with good beam quality is still the main challenge for scaling ultrabroadband OPCPA systems. The development of high-energy ps pump sources at kHz pulse repetition frequency (PRF) is important for energy and power scaling of existing mid-IR few-cycle OPCPA systems for phase-matched high-harmonic generation with high photon energies [2,3]. Multi-mJ ps Nd:YLF amplifier chains have been developed and used for several OPCPA systems at 1 kHz PRF [4,5], but further energy scaling at kHz PRF is difficult because of thermal beam distortions [6] and optical damage issues. Among several laser gain media for ultrashort pulse amplification, the Yb:YAG crystal is very attractive for scaling both energy and average power due to its suitable emission bandwidth for ps pulse amplification and good thermo-optical properties. The main drawback of the Yb:YAG crystal as a gain medium is its high saturation fluence at room temperature ( $\sim 9$  J/cm<sup>2</sup>). This problem has been solved by using thin-disk gain modules or cryogenically cooled bulk crystals. Recently 25 mJ, ps pulses at 3 kHz PRF were demonstrated directly from a thin-disk chirped-pulse ampli-

fication (CPA) Yb:YAG regenerative amplifier (RGA) [7] for OPCPA pumping. Meanwhile, based on cryogenic Yb:YAG laser technology [8], a 7.5 mJ, ps RGA at 10 Hz [9] and a 287 W, ps amplifier at 78 MHz [10] were demonstrated in terms of energy and average power scaling, respectively. Most recently, multipass amplification to  $> 1$  J of energy at 10 Hz was reported for application to x-ray laser pumping [11]. In this Letter, we demonstrate a multi-mJ, ps cryogenic Yb:YAG CPA laser system at kHz PRF, for the first time to our knowledge. A multi-mJ, ps RGA operating at 1–2 kHz PRF with excellent stability and beam quality is developed, and further amplification to 40 mJ at 2 kHz is demonstrated in a two-pass amplifier.

The optical layout of the high-power CPA ps cryogenic Yb:YAG laser system operating at 1–2 kHz PRF is illustrated in Fig. 1. The CPA chain consists of four subsystems: (a) a ps fiber seed source with a chirped fiber Bragg grating (CFBG) stretcher, (b) multi-mJ kHz cryogenic Yb:YAG RGA, (c) high-energy multipass cryogenic Yb:YAG amplifier, and (d) pulse compressor based on a multilayer dielectric (MLD) grating pair. The front-end oscillator is a homebuilt fs Yb-fiber laser at 78 MHz ( $\Delta\lambda = \sim 40$  nm at 1030 nm). The output pulses from the Yb-fiber laser are stretched to  $\sim 450$  ps by a CFBG with a  $\sim 1$  nm bandwidth centered at  $\sim 1029$  nm. A homebuilt single-mode Yb-fiber preamplifier in Fig. 1(a) compensates for the power loss in the CFBG caused by bandwidth filtering and coupling losses. An average power of 10 mW (0.12 nJ) is available for seeding the cryogenic Yb:YAG RGA. The cw-diode-pumped RGA in Fig. 1(b) is designed for amplification to  $\sim 10$  W at 1–2 kHz PRF. A 10 mm long Yb:YAG crystal with 2 at.% doping is pumped by a fiber-coupled (core diameter (diam) of 0.4 mm) laser diode (Laserline, GmbH) at 940 nm and cooled with liquid nitrogen in an evacuated Dewar. The pump beam size at the crystal is 1.2 mm in diam. The RGA is switched by a  $\beta$ -BaB<sub>2</sub>O<sub>4</sub>

Pockels cell with a quarter-wave voltage synchronized to the mode-locked pulse train. The output from the RGA is further amplified to tens of mJ in a multipass amplifier [10], as shown in Fig. 1(c), which can be operated in either a two- or four-pass configuration, as represented by paths (2) and (3), respectively. This amplifier has two 23 mm long Yb:YAG crystals with 2 at.% doping, pumped from both sides by two fiber-coupled (core diam of 0.6 mm) diode modules with an available total power of 700 W. The spot size at the crystal at the two-pass configuration is in the range of 2.5–2.8 mm to keep the amplified fluence at  $<1\text{ J/cm}^2$  for 50 mJ pulses. The damage threshold of high-energy dielectric mirrors is typically in the range of  $\sim 10\text{ J/cm}^2$  for 10–20 ns pulses, corresponding to  $\sim 1\text{ J/cm}^2$  for 100–200 ps pulses. The output fluence can be further reduced to  $<0.6\text{ J/cm}^2$  with larger spot sizes (3.3–3.5 mm) for a four-pass scheme—not attempted here. The accumulated  $B$  integral is estimated to be  $\sim 2\text{ rad}$  at 50 mJ with  $\sim 220\text{ ps}$  pulse duration for both two- and four-pass cases. Finally, the pulses are compressed by an MLD grating pair, as illustrated in Fig. 1(d). These gratings with 1752 lines/mm of groove density and  $>95\%$  of diffraction efficiency at 1030 nm over 10 nm of bandwidth can handle an average flux of up to  $\sim 1\text{ kW/cm}^2$  with negligible wavefront distortions. A throughput efficiency of  $\sim 80\%$  for this compressor was measured in the experiment.

The amplification characteristics of the RGA and the compressed pulse duration are shown in Figs. 2(a) and 2(b), respectively. For 2 kHz operation, a maximum average power of 16.4 W (8.2 mJ) at 100 W of pump power was obtained with a slope efficiency of 25%, while for 1 kHz operation, a maximum output energy of 13.2 mJ at 80 W of pump power was obtained with a slope efficiency of

22%. Because the fluorescence lifetime of the Yb:YAG crystal is  $\sim 0.85\text{ ms}$ , the slope efficiency at 1 kHz (1 ms interval) is slightly worse than that at 2 kHz (0.5 ms interval). However, the total efficiency at 1 kHz for  $<80\text{ W}$  pumping is higher than that at 2 kHz because of a lower amplification threshold that comes from less frequent cavity dumping. At maximum pump power, the RGA is saturated after 10–14 round trips. The shot-to-shot energy stability was as low as  $\sim 0.3\%$  rms for both PRFs. It was reported that the thin-disk kHz RGA in [7] was operated in the regime of “deterministic chaos” regarding PRF due to the low single-pass gain in a thin-disk gain medium and a correspondingly large number of round trips (120–150). In our cryogenic Yb:YAG RGA, no PRF instabilities were observed under normal operating conditions with proper dumping timing and cavity alignment. Grishin *et al.* [12] showed that RGAs with a relatively low number of round trips ( $<15$ ) are fundamentally more stable than those with large numbers of round trips, which accounts for the lack of PRF instabilities in our RGA. The gain narrowing of the RGA reduced the spectral bandwidth to 0.24 nm centered at 1029.2 nm. The pulse duration, taken from path (1) of Fig. 1 and compressed with  $\sim 60^\circ$  of incidence angle to the first MLD grating and  $\sim 1.5\text{ m}$  of grating separation, was 15 ps, as shown in the autocorrelation trace of Fig. 2(b), which is an  $\sim 2\times$  transform-limited pulse duration, 7.5 ps. Because of calibration offsets, the spectral

Fig. 4. (Color online) Average power versus pump power in the two-pass amplifier. The slope efficiency is 30%. Optical damage is observed for output powers at  $\sim 85$  W. The dotted and dashed curves show the output power for 12 and 6 W cw seeds for comparison.

window of the CFBG was actually centered at 1028.5 nm, whereas the amplified spectrum from the RGA was at 1029.2 nm, located at the edge of the spectral window of the CFBG. The imperfect compression with the pedestal seems to be attributed mainly to the group-velocity dispersion ripple at this spectral window edge. Thus, the pulse compression can be improved by using a new CFBG centered at 1029.2 nm or by heating the current CFBG for spectral tuning to a longer wavelength. The near- and far-field beam profiles from the RGA are shown in Figs. 3(a) and 3(b), respectively. At 2 kHz PRF we obtained a clean  $TEM_{00}$  fundamental mode with excellent focusing quality, as indicated by  $M^2$  of 1.08 and 1.06 for horizontal and vertical directions, respectively, measured using  $Z$ -scan analysis. The near-diffraction-limited far-field pattern of compressed beams shows that the MLD gratings induce no wavefront distortions, as expected.

For further amplification in the multipass amplifier, we changed to a CFBG with a  $2\times$  larger stretching ratio ( $\sim 220$  ps for 0.24 nm at the RGA). A longer stretching ratio increases both the surface and bulk damage thresholds. The spectral width of the RGA output pulses did not change with the new CFBG. The spot size at the Yb:YAG crystal in this amplifier is set to  $\sim 2.8$  mm diam for two-pass amplification. Figure 4 shows that a maximum power of 80 W (40 mJ) at 2 kHz PRF is obtained at 9 W seed power from the RGA with a slope efficiency of 30% and  $\sim 320$  W of pump power. The output power is limited by the damage of the chamber windows at  $\sim 85$  W. The cw amplification results using 12 and 6 W cw seed powers [dotted and dashed curves in Fig. 4] clearly indicate that the achievable output power is limited only by the damage threshold of amplifier optics. The compression of 40 mJ pulses is expected to generate  $\sim 32$  mJ,  $\sim 15$  ps pulses. 1 kHz operation was

not attempted because the amplifier could be damaged at lower average powers due to excessive pulse energies.

In summary, we demonstrated a ps multi-mJ RGA at 1–2 kHz PRF with excellent beam profile and shot-to-shot energy stability, and we further amplified the energy up to 40 mJ at 2 kHz PRF. This laser is a promising pump source for multi-mJ few-cycle OPCPA systems at  $2.2\ \mu\text{m}$  [5] and 800 nm via frequency doubling. Below-damage-threshold operation of the amplifier with pulse energies  $>50$  mJ seems to be feasible with four-pass operation and a larger spot size. Modification of the multipass amplifier toward a larger number of passes [11] and even larger stretching will enable further scaling of energy.
