Lunar Science for Landed Mission Workshop NASA Ames Research Center, 10-12 January 2018

Why the Lunar Farside?

- A whole new, unexplored world in Earth's backyard! Nearly 4× land area of the United States.
- Opportunity to demonstrate humanrobotic exploration strategies needed to explore the Moon, asteroids, & Mars.
- Farside includes the South Pole-Aitken basin – largest, deepest, & oldest impact basin in the inner solar system.
- Farside always faces away from Earth and is the only pristine radio-quiet site to pursue observations of the early Universe's Cosmic Dawn at ν~10-80 MHz.

Why Emplace Radio Telescopes on the Farside?

- Earth's Ionosphere (e.g., Vedantham et al. 2014; Datta et al. 2016; Rogers et al. 2015; Sokolowski et al. 2015)
 - Refraction, absorption, & emission.
 - Spatial & temporal variations related to forcing action by solar UV & X-rays
 => 1/f or flicker noise acts as another systematic or bias.
 - \circ Effects scale as v^{-2} so they get **much worse** approaching 10 MHz.

Radio Frequency Interference (RFI)

- RFI particularly problematic for FM band (88-110 MHz).
- Reflection off the Moon, space debris, aircraft, & ionized meteor trails are an issue everywhere on Earth (e.g., Tingay et al. 2013; Vedantham et al. 2013).
- \circ Even in LEO (10⁸ K) or lunar nearside (10⁶ K), RFI brightness T_B is high. Need to suppress RFI by at least -80 dB to observe cosmological signal.

Astrophysics Community Surveys Advocate for Low Radio Frequency Cosmology on the Farside

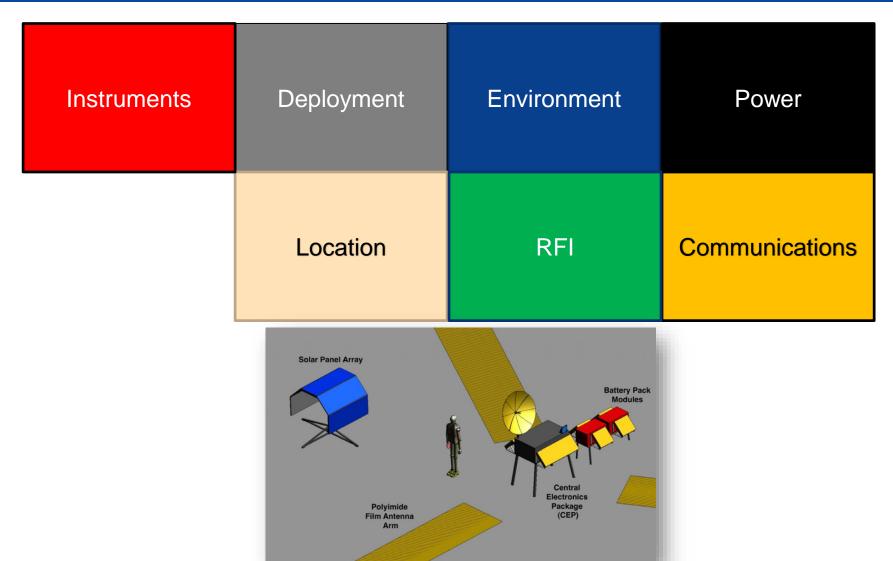

- •Astrophysics Decadal "New Worlds, New Horizons": "A great mystery now confronts us: When and how did the first galaxies form out of cold clumps of hydrogen gas and start to shine—when was our Cosmic Dawn?"
- •NASA Astrophysics Division Roadmap (2013): How Does our Universe Work?
 - •**Small Mission:** "Mapping the Universe's hydrogen clouds using 21-cm radio wavelengths via a *lunar orbiter* observing from the farside of the Moon".
 - •Visionary Era: "Cosmic Dawn Mapper (21-cm lunar surface radio telescope array) … Detailed map of structure formation in the Dark Ages via 21-cm observations".

High-Level Trade Space for Lunar Radio Telescopes

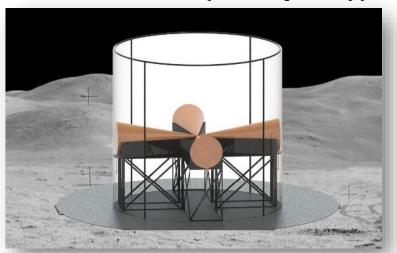

Instruments

<u>Hydrogen Cosmology Global</u> <u>Signal Telescope</u>

- 10-100 MHz
- Polarimeter
- Ground Plane
- Operation temperature = -250 C to +150 C
- Power < 200 W
- Data storage (< 1 GB per 24 hr)
- Data transmission (< 1 GB per day)

Cosmic Dawn Mapper

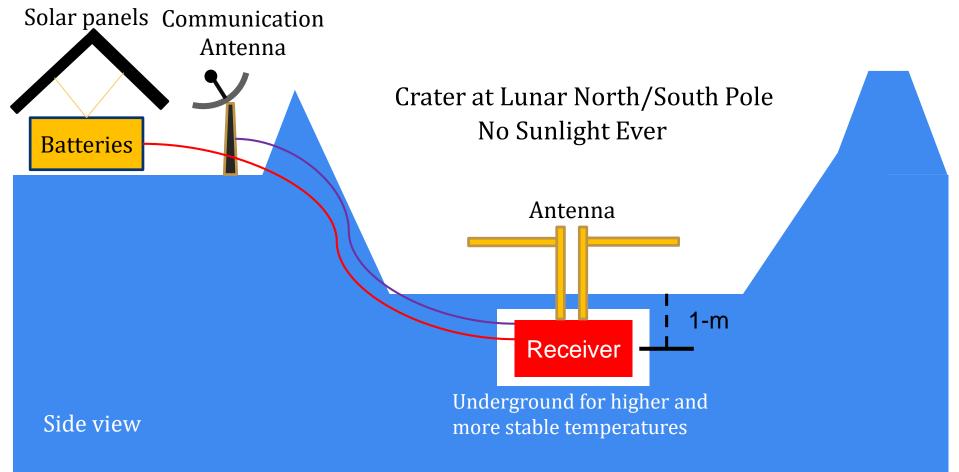

- At 10 MHz, 1° resolution requires ~2 km baselines
 - Filled aperture: 1 element / 3600sq. m
 - Circle layout: 1 element / 6 meters
- 10⁵ square meters collecting area requires
 >1000 dipoles
- 1000 dipoles * 2 pol * 20 MHz bandwidth →
 ~40 GB/s
- Power $\sim 2.5 \text{ kW}$

Can a Low Frequency Antenna be Sited in a Polar Crater?

Hit by Sunlight (Periodically or continuously)

Radio Frequency Interference (RFI) within a crater at the Lunar Pole

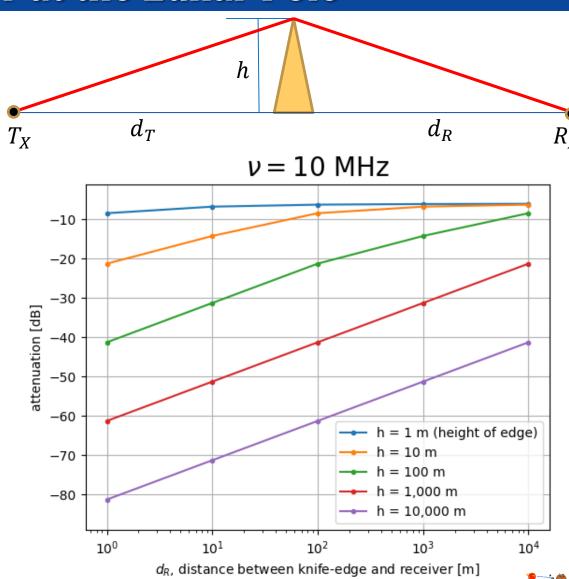

Simulating RFI in a polar crater, with the edge of the crater as a knife-edge. The transmitter (T_x) is on Earth, and the receiver (R_x) is in the crater, at a distance d_R from the edge. The RFI attenuation at R_x is computed using:

$$x = h \sqrt{\frac{2}{\lambda} \left(\frac{1}{d_T} + \frac{1}{d_R} \right)}$$

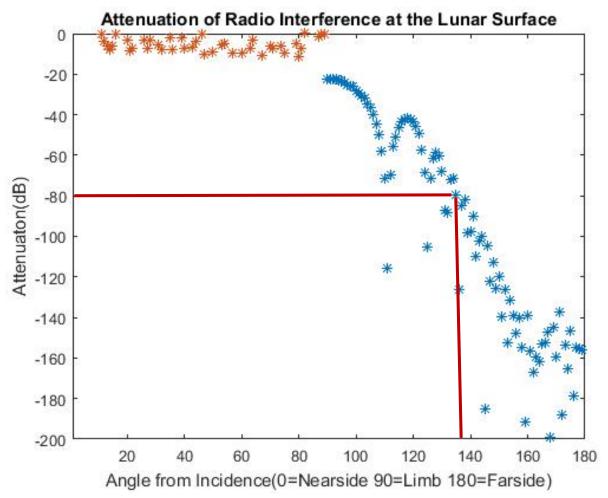

Attenuation
$$A = 0$$
, if $x < 0$
 $A = 6 + 9x + 1.27x^2$, if $0 < x < 2.4$
 $A = 13 + 20 \log(x)$, if $x > 2.4$

Problems:

- Insufficient attenuation
- Crater rim blocks sky & corrupts antenna beam.

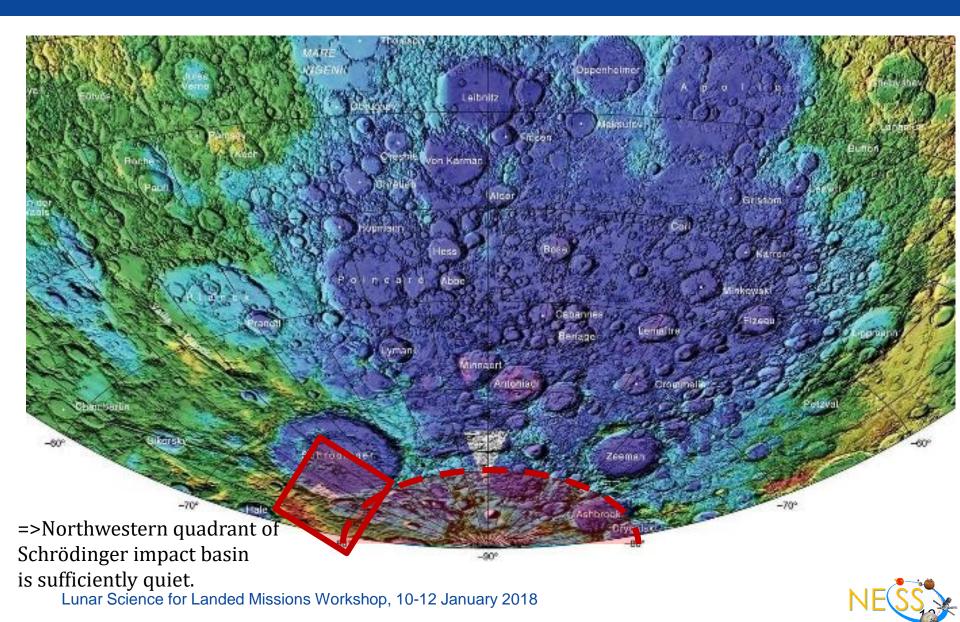

Global Farside Radio Frequency Interference

From simulation by Datta et al. (2018). At latitude of -80° and frequency of 1 MHz, -80 dB is achieved at \approx 45° from the lunar limb

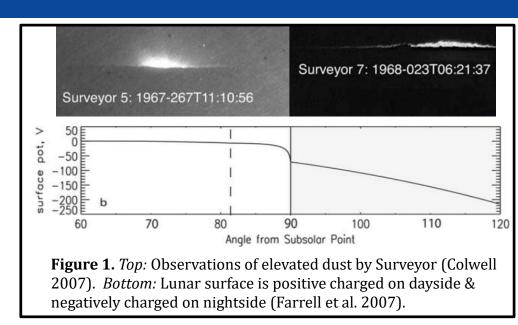

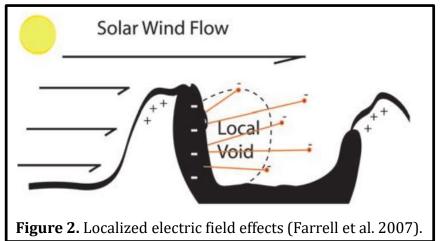

RFI Constraints on Telescope Location

The Lunar Environment

- Data are required for the electrical conductivity & permittivity of the regolith, to model the response of low-frequency antennas.
- On dayside, UV & X-rays positively-charge surface with 1–5 V whereas nightside has negative surface potential with ≥-500 V. Charged dust grains are levitated (**Fig. 1**).
- Changes in surface potential by 10x occur during solar energetic particle event
- => Need to stay grounded to plasma.
- Elevated dust **(Fig. 1)** can cause visibility problems, especially for teleoperation.
- Strong electric fields occur in terminator & shadowed regions. Gradients cause negatively charged particles to accelerate away from the surface (**Fig. 2**). Effect on electronics mitigated by placing electronics underground (<1 m), & within Faraday cages.

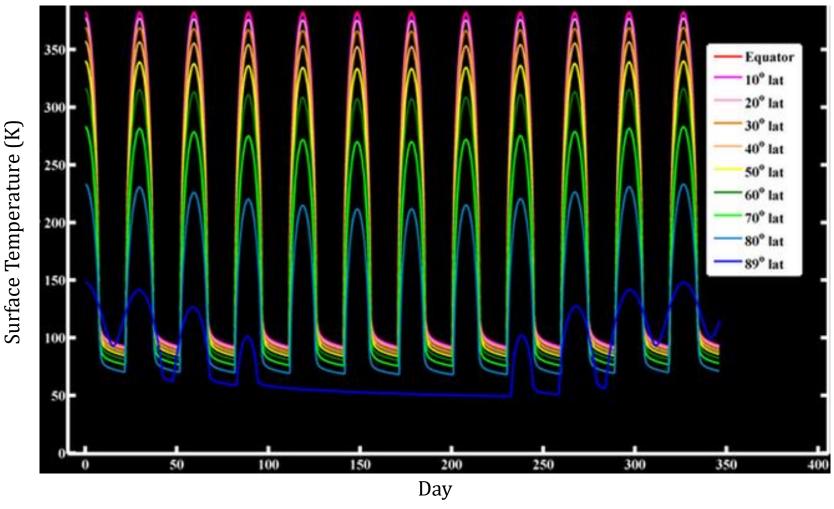

The Lunar Environment

Power, Communications, and the Deep Space Gateway

Power Requirement: 0.2 - 2.5 kW

- Assuming above accounts for instrument and thermal control electronics.
- Battery + solar panels (outside crater if necessary).
- RTG (radioactive).
- Power beamed from Deep Space Gateway.

Data Downlink Requirement: < 1 GB per 24 hr to 40 GB/sec

• Use Deep Space Gateway as communication relay for first generation instruments.

Summary and Conclusions

- Lunar Farside is the only location in the inner solar system quiet enough to conduct observations of Cosmic Dawn down to ∼10 MHz.
- Possible instruments: Single antenna for Global 21-cm Signal and Array of Dipoles to measure the spatial structure in the early Universe.
- Polar craters do not provide enough attenuation of RFI for siting a low frequency radio telescope.
- But, locations <80° latitude and 45° from the lunar limb on the farside are suitable sites. This includes a NW quadrant of Schrödinger.
- Lunar environment:
 - Elevated dust and changes in surface potential are possible issues.
 Need to stay grounded to local plasma. Siting electronics below ground and/or in Faraday cages are probably needed.
 - Day/night temperature variations are an issue, but for elevations
 <70° temperatures vary from 0°C to -150°C.
- Power, communication, and deployment of an initial low radio frequency observatory can be facilitated by the Deep Space Gateway.
