

Robustly Constraining the Global 21-cm Signal using Pattern Recognition and Bayesian Inference

David Rapetti

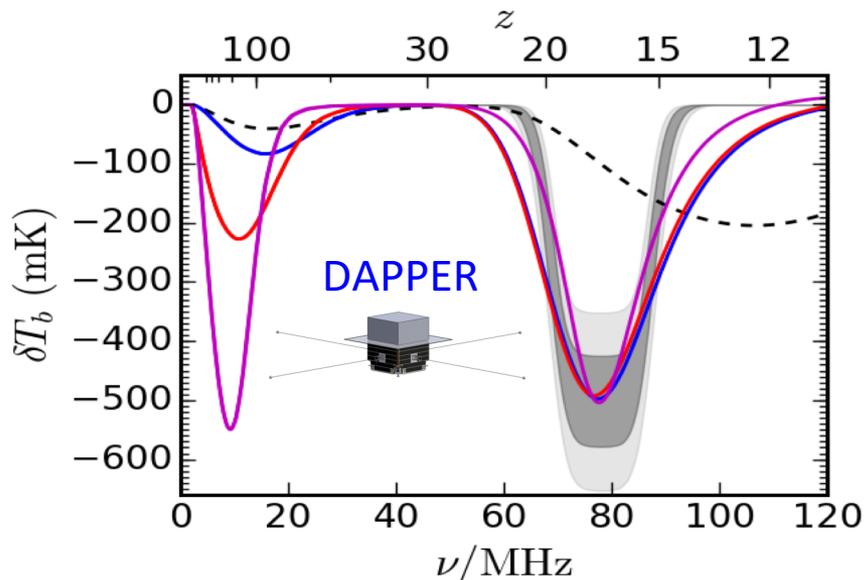

NASA Ames Research Center
Universities Space Research Association
University of Colorado Boulder

In collaboration with other key pipeline builders:

Keith Tauscher, Jack Burns
University of Colorado Boulder

OUTLINE OF THE CHALLENGES

- Accurately & precisely extracting & constraining the **small global 21-cm signal** from within a **foreground 4-6 orders of magnitude larger**.
- **Limited available information** on both the signal and the systematics of the experiment, including **potential overlaps** between the spectral shapes of the signal and systematics.

The Dark Ages Polarimeter Pathfinder (DAPPER) is a NASA SmallSat mission concept for hydrogen cosmology from the radio pristine lunar far side (see Burns' talk earlier).

78 MHz trough reported by EDGES in gray.

Standard astrophysical model (**black, dashed curve**) inconsistent with EDGES data.

Exotic physics models of the **Dark Ages** trough consistent with the EDGES signal (color curves; credit J. Mirocha).

OUR CURRENT SOLUTIONS: PIPELINE PUBLICATIONS

- Pipeline series Paper I, II, III (published), and IV (in preparation):
 - Paper I: [Global 21 cm Signal Extraction from Foreground and Instrumental Effects. I. Pattern Recognition Framework for Separation Using Training Sets](#) (2018, ApJ, 853, 187)
 - Paper II: [Global 21 cm Signal Extraction from Foreground and Instrumental Effects. II. Efficient and Self-consistent Technique for Constraining Nonlinear Signal Models](#) (2020, ApJ, 897, 174)
 - Paper III: [Global 21 cm Signal Extraction from Foreground and Instrumental Effects. III. Utilizing Drift-scan Time Dependence and Full Stokes Measurements](#) (2020, ApJ, 897, 174)
- Minimum Assumption Analysis (MAA) paper (see Tauscher's talk later):
 - [Formulating and Critically Examining the Assumptions of Global 21 cm Signal Analyses: How to Avoid the False Troughs That Can Appear in Single-spectrum Fits](#) (2020, ApJ, 897, 132)

modes to use
in the fit

DATA COMPONENT TRAINING SETS AND SVD MODES

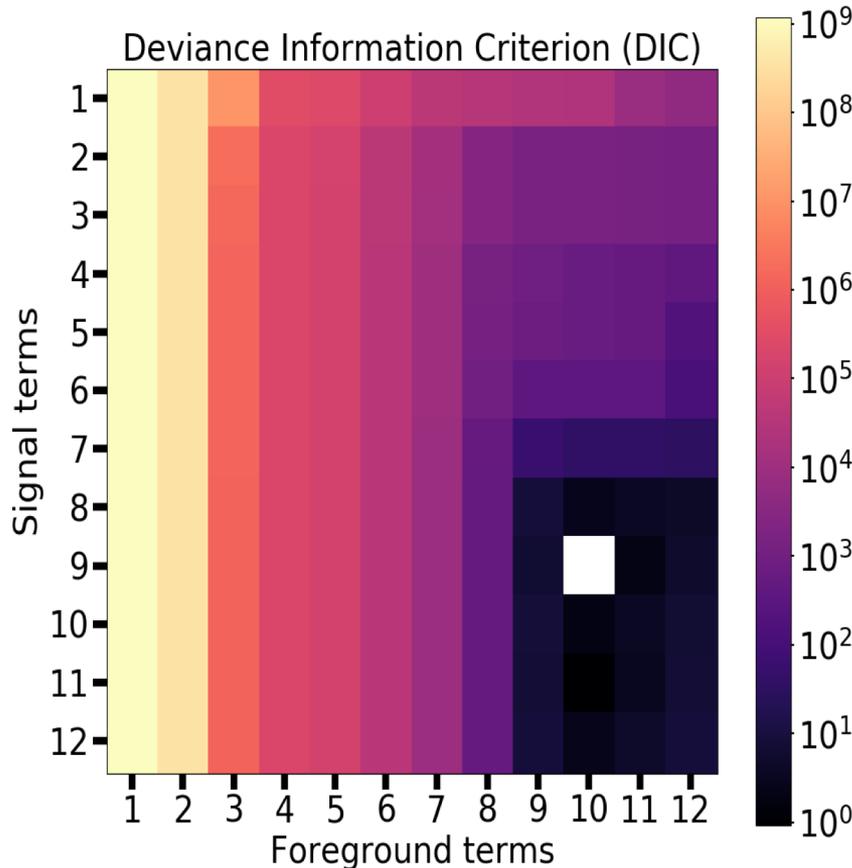

Tauscher, Rapetti, Burns, Switzer (2018; Paper I)

- The bottom panels show the [first six SVD eigenmodes](#) obtained from the training sets above in black.
- SVD modes [ordered from most to least important](#). For foreground modelling, [see Hibbard's talk tomorrow](#).
- For an overall linear model, we [choose each component's number of SVD modes](#) using an information criteria.

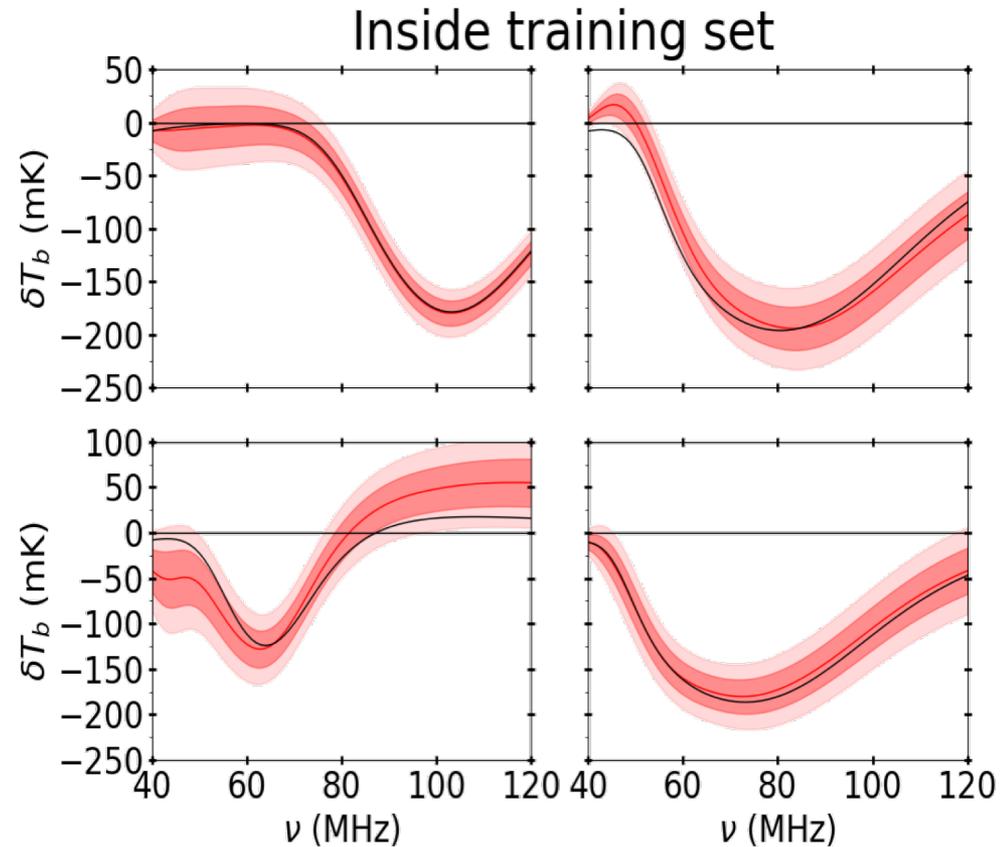

MODEL SELECTION (NUMBER OF MODES) AND LINEAR, ANALYTICAL SIGNAL EXTRACTION

Tauscher, Rapetti, Burns, Switzer (2018; Paper I)

$$\text{DIC} = -2 \ln \mathcal{L}_{\max} + 2p$$

(See also Bassett's talk afterwards)

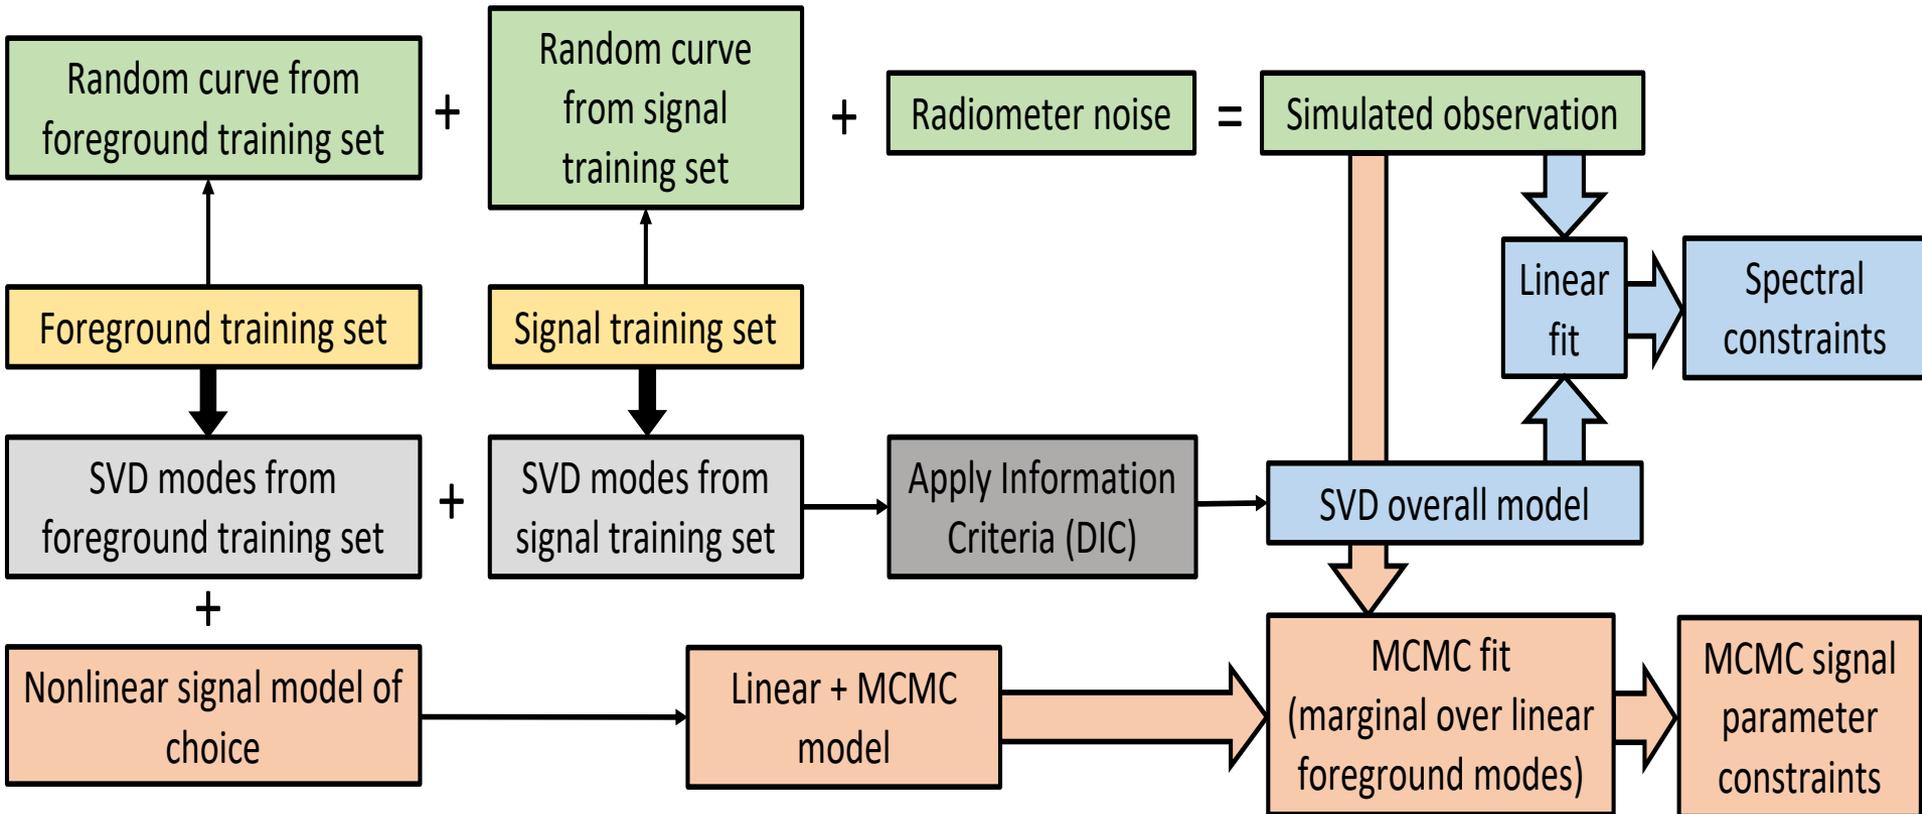

Black curves: Input signals; **red:** estimates; **dark/light red bands:** 68/95% confidence intervals

JOINT MCMC FIT OF NONLINEAR SIGNAL MARGINALIZING OVER LINEAR BEAM-WEIGHTED FOREGROUND

- In [Paper II](#) (Rapetti, Tauscher, Mirocha & Burns, 2020), we present a new technique converting spectral constraints into **constraints on any given nonlinear signal parameter space**.
- We analytically find a **joint linear fit** of the signal and systematics (currently, beam-weighted foreground) and used as starting point (mean and covariance) for a **simultaneous, nonlinear Markov Chain Monte Carlo (MCMC) fit**.
- At each step of the MCMC fit, we **marginalize** over the **coefficients to the SVD foreground modes**. This allows us to straightforwardly use a large number of foreground parameters, while **efficiently** exploring the signal parameter space.
- This calculation is **exact** and provides a natural separation of **linear nuisance parameters without a need for a parametric model** and nonlinear signal parameters to be numerically sampled. A **similar separation between linear and nonlinear parameters** can be performed in **receiver** modeling ([Paper IV](#), in prep.).

CONSTRAINING SINGAL PARAMETERS (PAPER II)

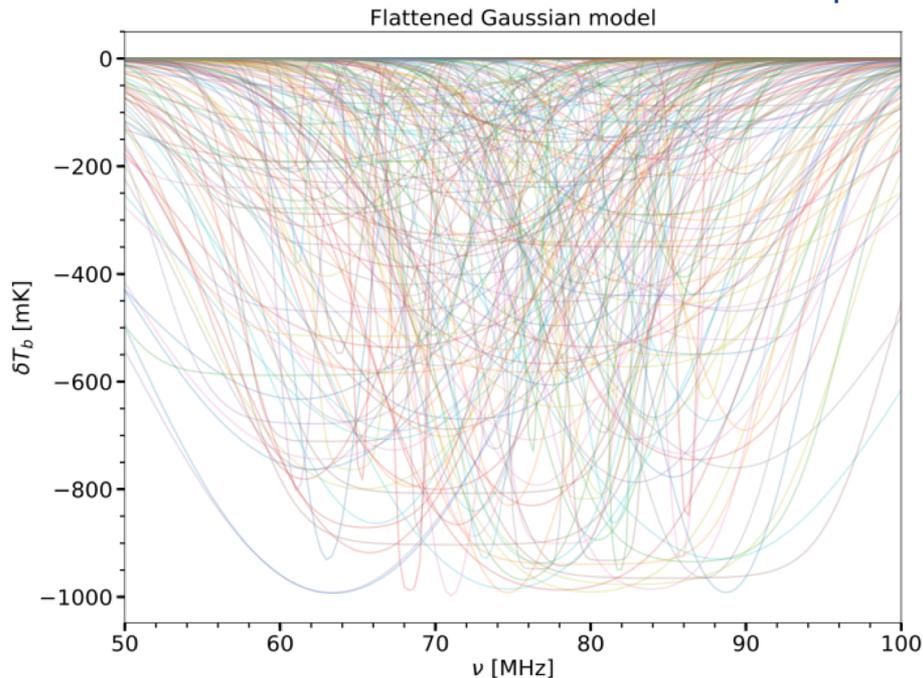

Rapetti et al. (Paper II)

Find the code **pylinex** in this link: <https://bitbucket.org/ktausch/pylinex>

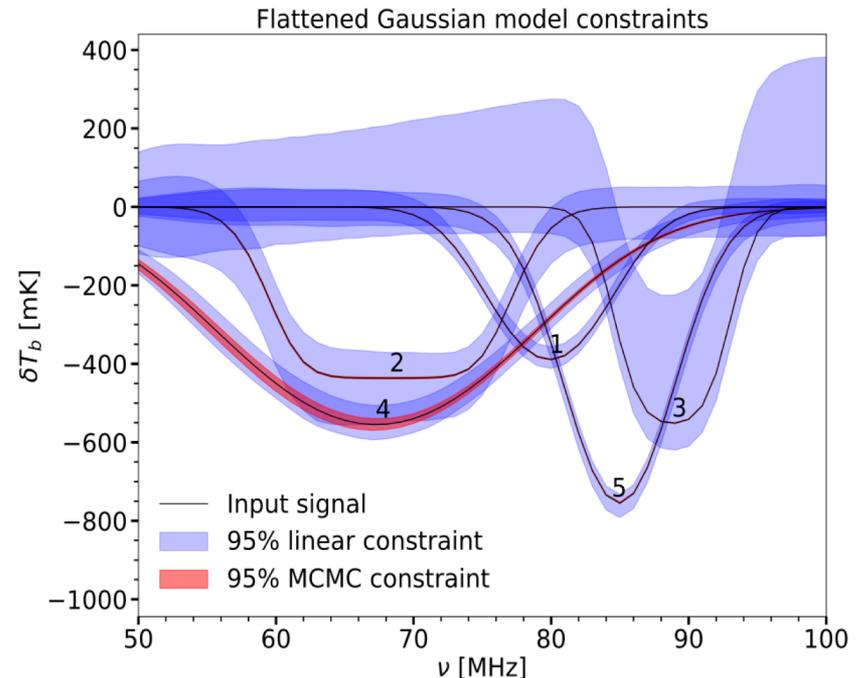

GLOBAL 21-CM SIGNAL MODEL: FLATTENED GAUSSIAN

Rapetti et al. (Paper II)

Sample of 200 curves from the training set for the flattened Gaussian model.

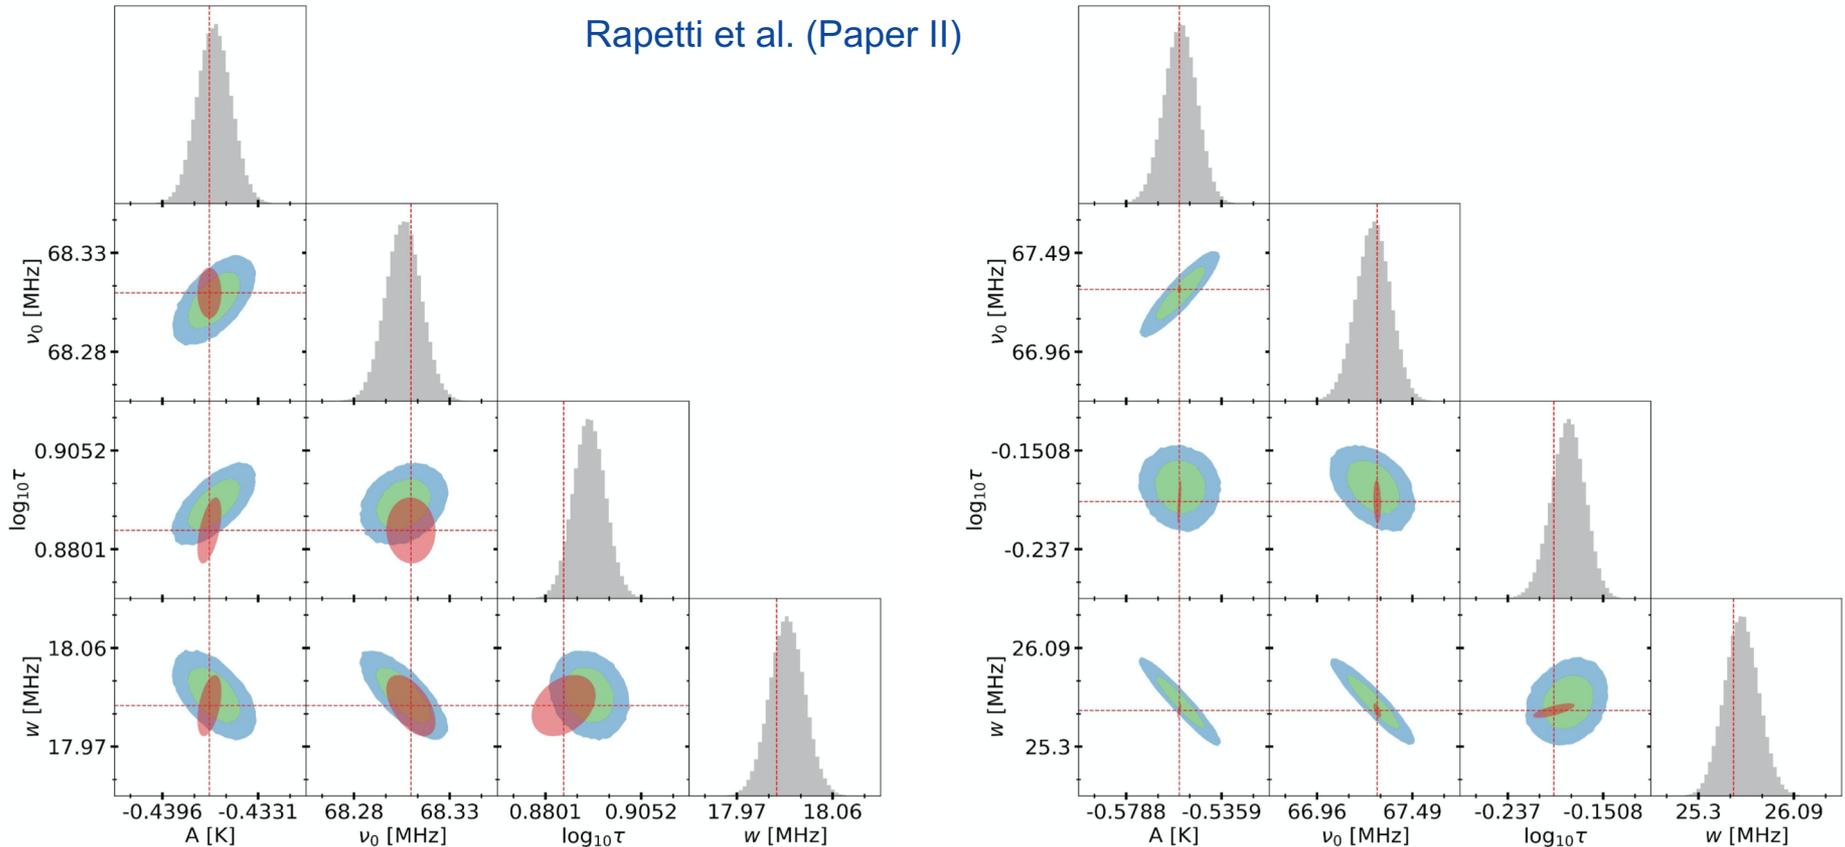

A uniform (-1, -0.1) K
 ν_0 uniform (60, 90) MHz
 w uniform (1, 30) MHz
 τ exponential (1)

- 5 random cases successfully recovered
- 95% C.I. in blue for the linear fit (SVD signal & foreground modes) and red for the MCMC fit (nonlinear signal model & SVD foreground terms marginalized over)
- In the linear fits, the 95% C.I. correspond to 8.75σ .

FLATTENED GAUSSIAN MODEL: FULL MCMC PARAMETER CONSTRAINTS

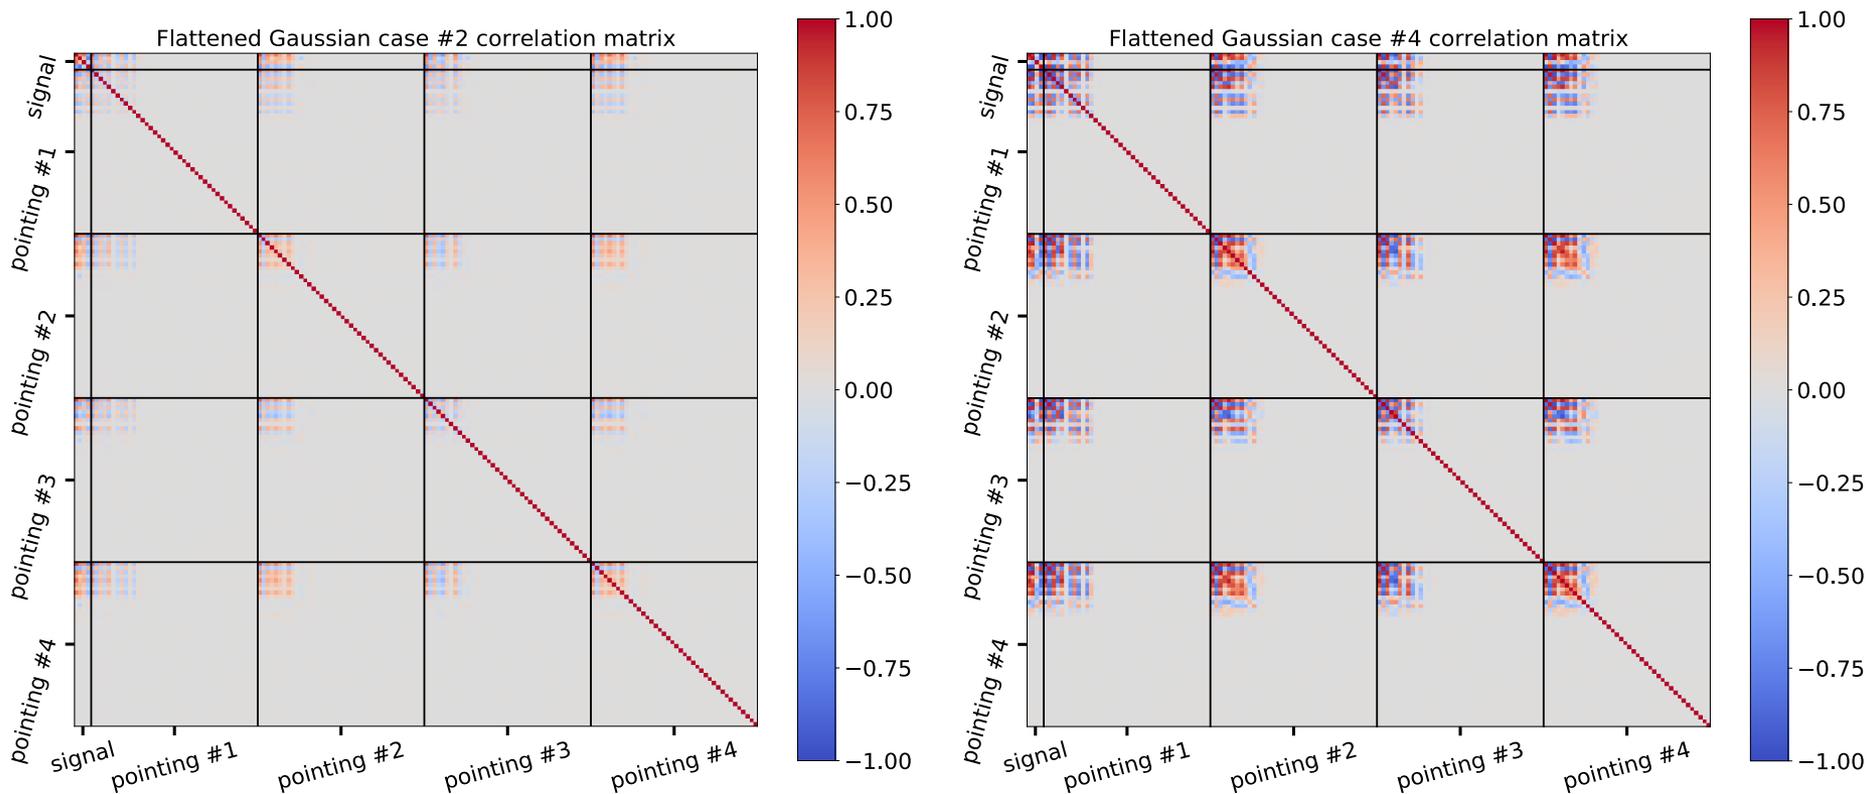

Rapetti et al. (Paper II)

- 1D (gray) and 2D (68/95%) MCMC posterior parameter constraints.
- **Red contours:** represent 95% errors for **statistical noise alone**.
- **Red, dashed lines:** mark the **input parameters**.
- In case FG4 (right) the systematics clearly play a larger role than in case FG2 (left).

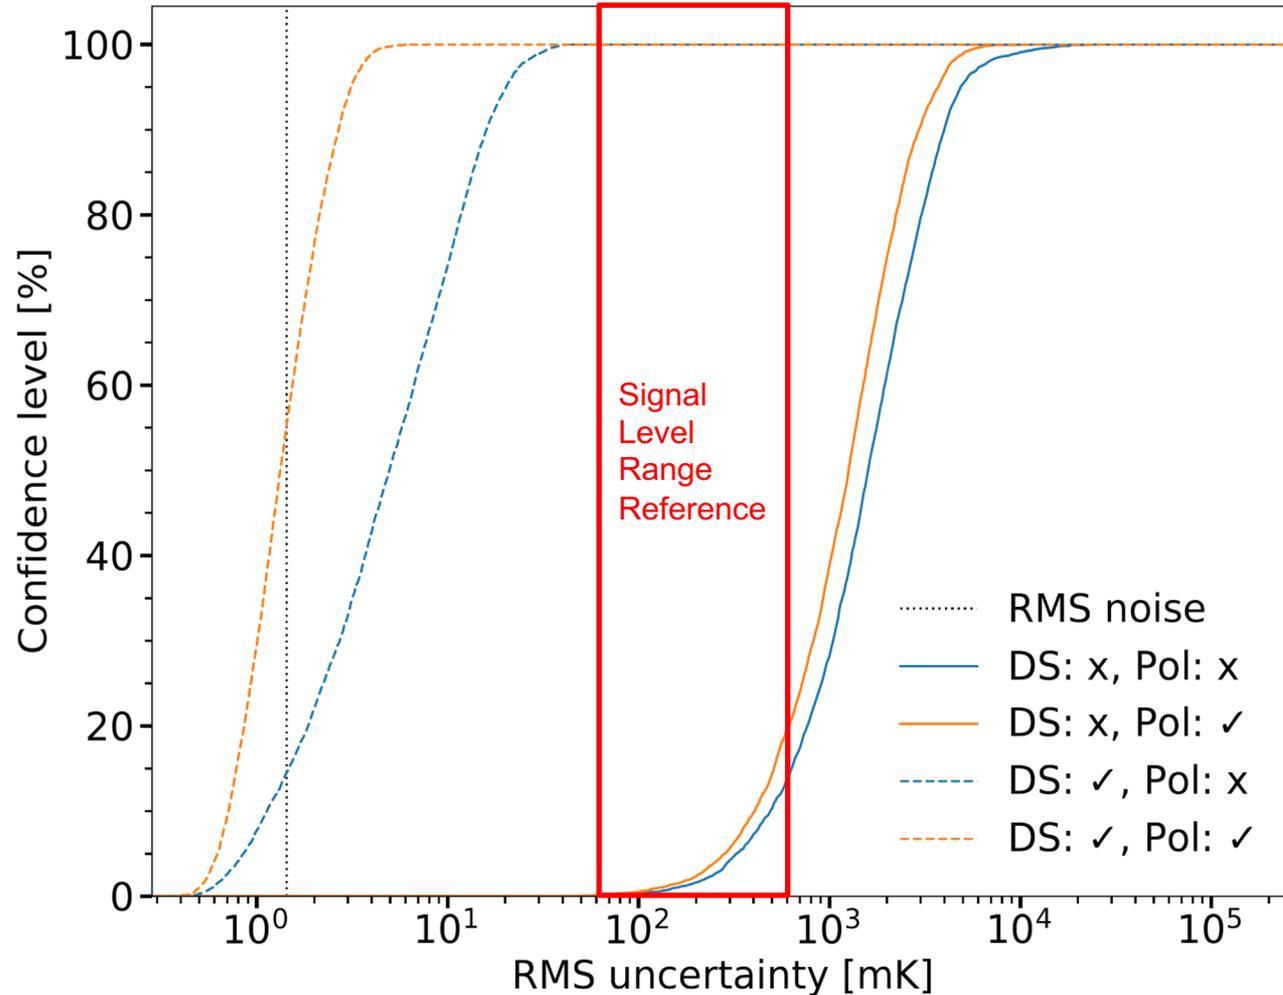

FLATTENED GAUSSIAN MODEL: CORRELATION MATRICES

Rapetti et al. (Paper II)

- Correlation matrices for the MCMC fits of FG2 (left) and FG4 (right).
- Matching the previous slide, these show stronger correlations for FG4 versus FG2.
- **4 signal & 160** (40 per 4 pointings) **foreground** parameters. Our **marginal MCMC** reduced the MCMC parameters from **164 to 4**.
- Most foreground parameters (above a certain mode order) **have negligible correlations** (in gray), becoming thereby irrelevant thanks to the down-weighting power of **foreground priors**.

MEASUREMENT STRATEGY EFFECTS ON UNCERTAINTIES (PAPER III)

- Each CDF for 5000 fits
- DS: Drift-scan time dependence (Dashed lines: 25 bins in LST)
- Pol: Full polarized Stokes measurements (in blue)
- Both time dependence and polarization measurements provide marked benefits

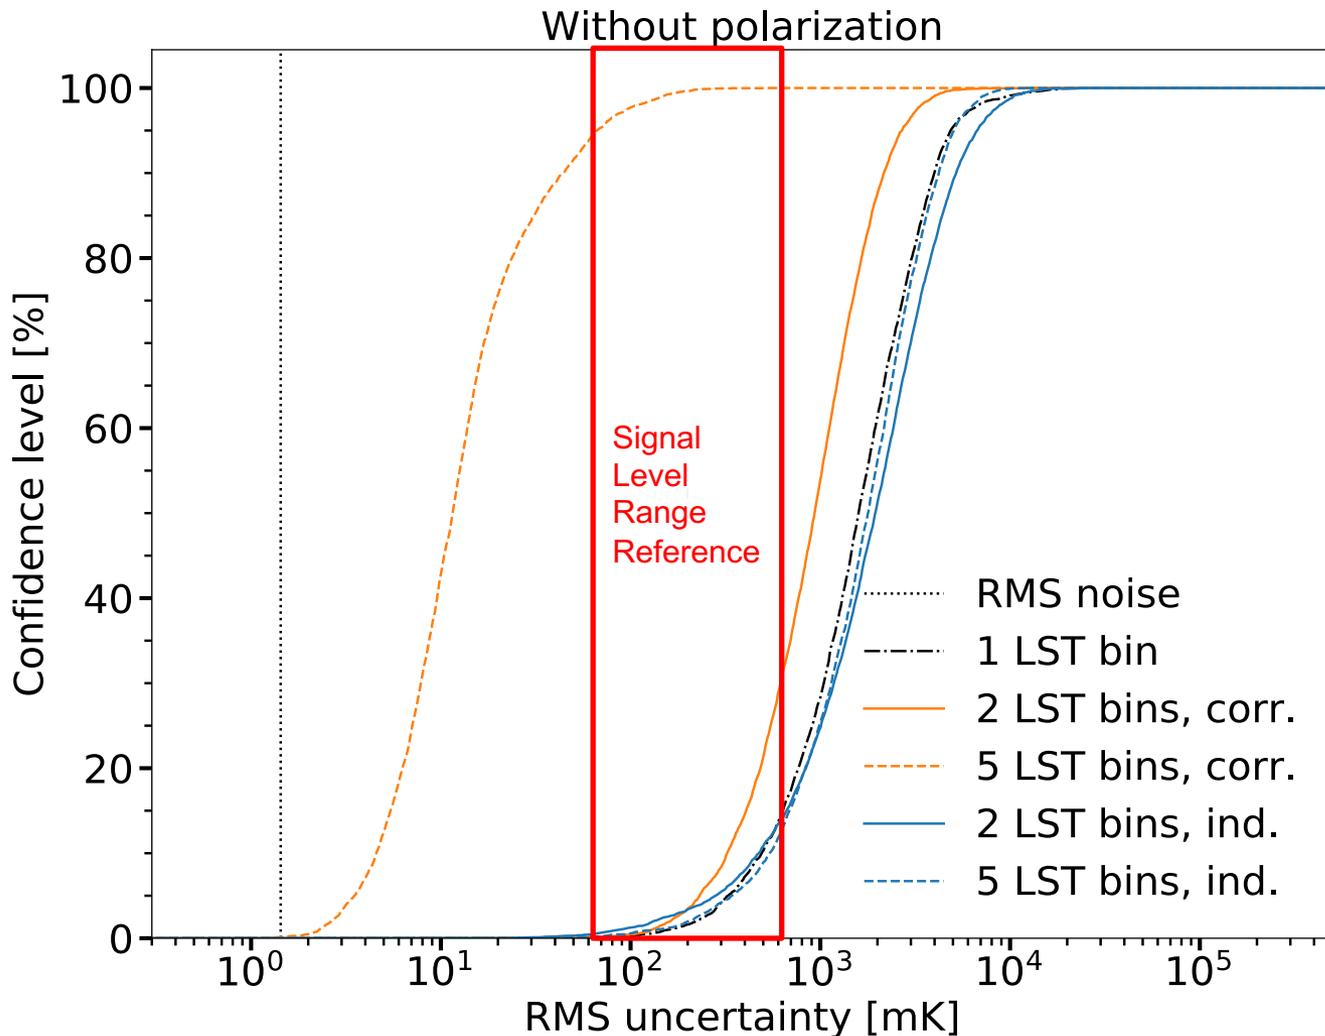

Tauscher et al. (Paper III)

UTILIZING THE CORRELATIONS BETWEEN SPECTRA

- Without polarization
- Orange: Correlated LST bins
- Blue: Independent LST bins
- Benefiting from correlations between LST bins is critical for best constraints

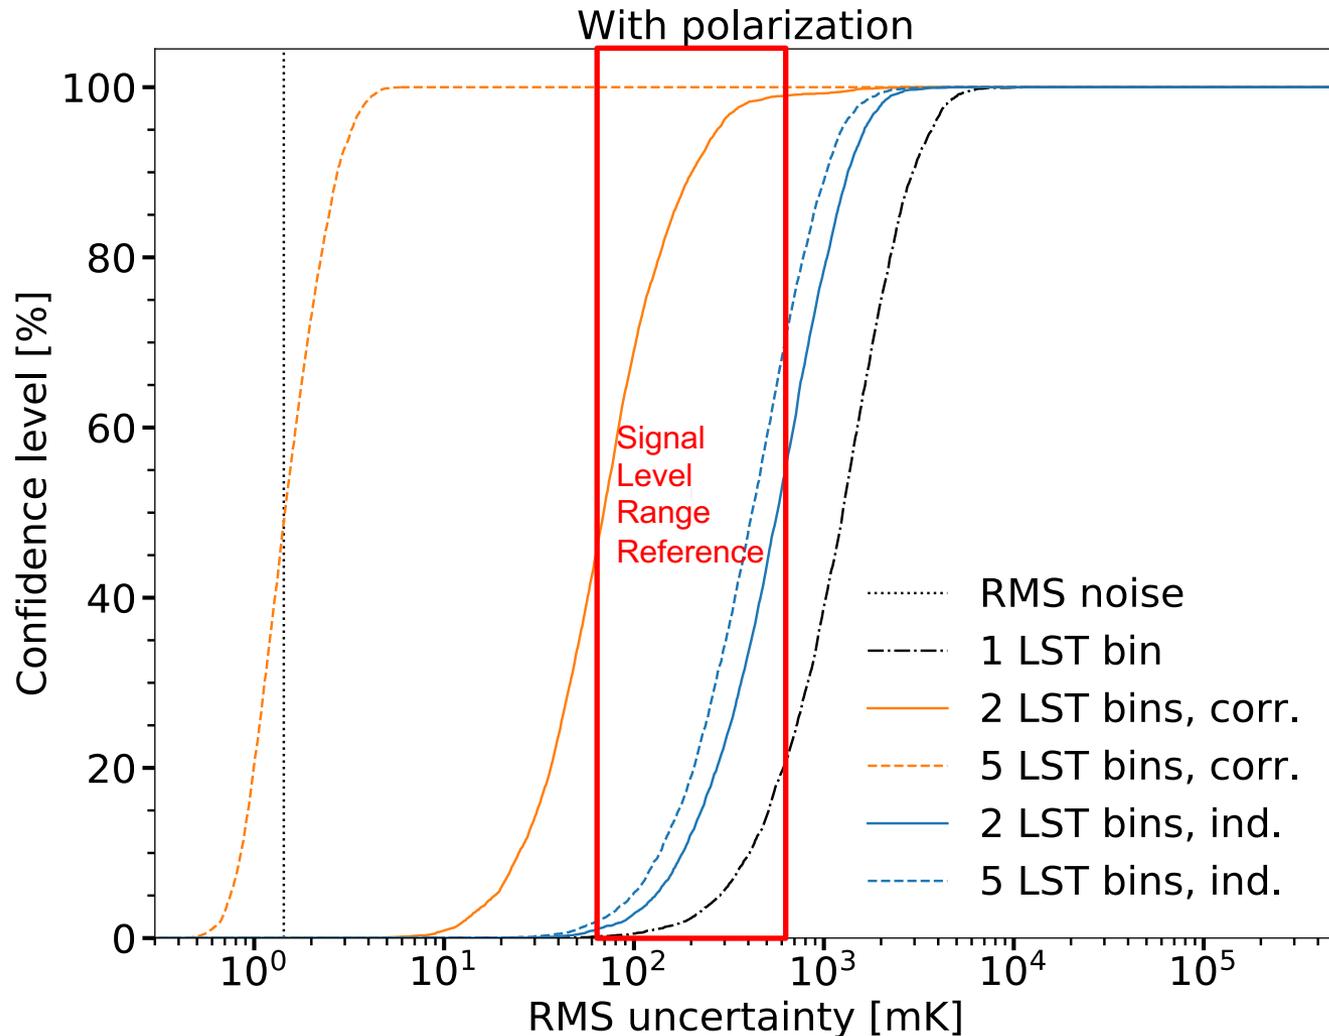

Tauscher et al. (Paper III)

BENEFITS OF OUR METHODOLOGY

- We can use a **large number of correlated spectra** at once, create models **specifically suited** for a given experimental dataset, form training sets **arbitrarily complex** (avoiding the necessity for smooth, phenomenological foregrounds), and include **beam effects directly into the model** (instead of having to remove them).
- SVD factorizes a training set providing the **optimal vector basis** to fit it.
- We employ a **linear, fast, analytic methodology** to separate the global 21-cm signal from systematics, properly accounting for their potentially large overlaps, to estimate the **starting point of a full MCMC search** of any chosen **nonlinear signal model**.
- We utilize the linear coefficients of the **SVD beam-weighted foreground model** to properly and efficiently (in terms of convergence) incorporate this modeling by **marginalizing over these generally large number of parameters** at each step of our MCMC signal calculation.
- We benefit from the use of **correlated foreground spectra via multiple sky views or Stokes parameters** to differentiate between foreground & signal, significantly lowering uncertainties.
- Our **statistically rigorous pipeline** is able to extract the global 21-cm signal while modeling signal & systematics using **detailed training sets** from theory, simulations and observations.
